Are trained individuals more likely to perform bystander CPR? An observational study

Kayo Tanigawaa, Takulwamia, Chika Nishiyamab, Hiroshi Nonogic, Takashi Kawamuraa

100/04/30

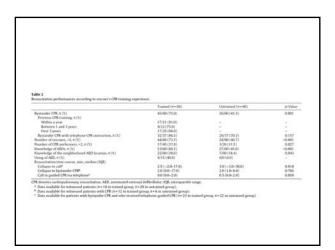

Introduction

- High mortality of OHCA cases is an important clinical issue
- Successful resuscitation after OHCA depends on early initiation of CPR and defibrillation
- Bystanders CPR could potentially double survival after OHCAs
- The association of people's CPR training with their subsequent resuscitation performances and patient outcomes after OHCA.

Methods

- Patient: OHCAs of intrinsic origin
- · Rescuer:

The one who called an ambulance or the one who performed CPR

Results-rescuers

- The proportion of bystander CPR significantly greater in the trained rescuer group than in the untrained rescuer group (75.0% vs 43.3%)
- In the trained rescuer group, the proportion of bystander CPR was greater in those with recent CPR training.
- Rescuers who had experienced previous CPR training were 3.4 times more likely to perform CPR (compared with those without such experience).

Results-rescuers

Attitudes toward AEDs
 The proportion of those who had knowledge of AEDs and the neighborhood AED location were significantly greater in the trained rescuer group than in the untrained rescuer group. 6 rescuers in the trained rescuer group actually used an AED, while none in the untrained rescuer group used it.

Results-rescuers

- Middle-aged (40–64) years rescuers and female patients were associated with lower proportion of bystander CPR.
- ☆Surprisingly, patients with witnessed arrest were less likely to receive bystander CPR compared to those without it

Results-patients

- One-month survival was 13.3% in the trained rescuer group, while 8.3% in the untrained rescuer group
- Neurologically favorable one month survival was 3.3% in the trained rescuer group, against 1.7% in the untrained rescuer group
- Number of survivors too small to evaluate the difference between the groups.

Discussion

 In this study, the EMS personnel interviewed the actual rescuers at the scene which assured the quality of data and minimized recall biases.

Discussion

 The experience of CPR training could improve rescuers willingness to perform CPR and could result in better patient outcomes after OHCA.

Discussion

- Providing CPR instructions
 Previous studies reported that CPR instruction by dispatchers could encourage lay rescuers to perform CPR and improve the quality of CPR performed by bystanders with previous CPR training
- Both CPR training and telephone CPR instruction could increase bystander CPR.

Attitudes toward AED
 CPR training increased the knowledge of not only an AED itself but also the neighborhood AED locations, which suggested that CPR training engaged their attention to AEDs

Discussion- patients with witnessed arrest were less likely to receive

- bystander CPR

 One potential explanation for this paradox maybe patients' agonal breathing in the early stage of cardiac arrest, which is observed in nearly half of witnessed cardiac arrests and can easily mislead rescuers about patient vital states. Other multiple reasons (e.g., panic, fear of failure, embarrassment and so on) could decrease the willingness of bystanders to start CPR
- Improvements in the contents of CPR training program such as the recognition of agonal breathing should also be taught to increase CPR

Discussion-limitations

- data on the quality of bystander CPR were unknown in this study.
- bystander information was obtained by interviewing the bystanders themselves, and some recall bias might exaggerate our study results
- might still be unmeasured but influential confounding factors

Conclusion

- rescuers who had CPR training were more willing to perform CPR at the OHCA scenes than those who had not.
- CPR by bystander is strongly linked to improved patient survival, CPR training could yield better outcomes after OHCA
- Further studies are needed to prove the effectiveness of CPR training on survival.
